Vaccine Propaganda Vs Vaccine Truth

Vaccines do not need much in the way of advertising; they have a way of selling themselves. After all, the majority of people believe that they are absolutely necessary. How did these beliefs come to be so entrenched in the minds of the public?

Most Americans don’t realize they have a choice. Day care centers and schools ask for proof of vaccination before registration and pediatricians and general physicians treat vaccines as a fundamental and necessary part of basic health care. The pharmaceutical industry heavily funds medical schools and medical research, influencing the perceptions of the medical profession, convincing them that vaccines are safe and effective. They, in turn, influence public perception. This kind of propaganda is highly effective when neither doctors nor parents take the time to do the research.

*Propaganda does not deceive people; it merely helps them to deceive themselves.* — Eric Hoffer

Vaccines Do Not Cause Autism

If vaccines do not cause autism then why is autism listed as one of the possible side effects on vaccine warning inserts? If we read the warning inserts, we can begin to see vaccines for what they really are - dangerous pharmaceuticals. For instance, encephalitis is an adverse reaction listed for many different vaccines. When severe swelling of the brain occurs, it can cause autism.

There have been dozens of studies by independent scientists that show vaccines increase the risk of autism. To the layperson, yes, vaccines do cause autism. To a scientist, the
word “cause” is a word that is not used in the same manner as lay people would use it. As Judy Mikovitz, an experienced vaccine researcher explains:

Ah, no. Vaccines definitely don’t cause autism. And we’ve talked, and we should talk, about this word “cause.” Because in my forty years or so working with cancer and HIV/AIDS and other chronic diseases there are two words that we don’t use. We don’t use cause and we don’t use cure. Because in order for something to be causative by the scientific definition that we use, every single case of the disease must have a vaccine origin.

And of course, you yourself just said 7 of 10 moms feel that the change in their child’s behavior and health occurred following a vaccination, but that’s still not every case. So what we usually say is associated.

So if you change that question and you ask me are vaccines associated, do they play a role in the brain damage and the immune damage that results in autism, I would say absolutely. And there is a ton of data to back that up.

Though there have been many studies demonstrating no link between vaccines and autism, these studies were funded by the pharmaceutical industry or the U.S. government. Both the U.S. government and the pharmaceutical industry have a vested interest in manipulating the outcomes of these studies to show the results that they want. This may sound a little conspiratorial, but they have been caught doing exactly that, manipulating data to make vaccines appear to be safer than they actually are. One such example of this is the study identified by William Thompson, the CDC whistleblower, but his involvement in vaccine cover-ups is just the tip of the iceberg. U.S. regulatory agencies are staffed by industry insiders who are constantly seeking to push vaccines on the public under the guise of the “greater good”.
In order to find reliable guidance, many people look to independent scientists for guidance. However, genuinely independent research is very hard to find. When universities are heavily funded by the pharmaceutical industry, they are not conducting truly independent research either. They do often conduct pro vaccine studies claiming that vaccines do not cause autism, but this is what they are paid to do. We don’t need to be fooled by vaccine propaganda. All we need to do is read a vaccine warning insert or take a look at the FDA’s website. They readily admit that the vaccine can cause all manner of adverse reactions:

"Adverse events reported during post-approval use of Tripedia vaccine include idiopathic thrombocytopenic purpura, SIDS, anaphylactic reaction, cellulitis, autism, convulsion/grand mal convulsion, encephalopathy, hypotonia, neuropathy, somnolence and apnea."

The FDA directly contradicts the talking heads on CNN and other mainstream media outlets. The reason why is simple: over 70% of mainstream media’s advertising revenue comes from the pharmaceutical industry. Media reports what they are told to report, even when it’s not true. They know most of their viewers will not take the time to do the research.

Vaccines Have Played a Role in the Historical Decline of Infectious Disease

Malnutrition, food poisoning, high parasite exposure, abysmal hygiene, unreliable or non-existent trash removal, unclean drinking water, plumbing infrastructure that ranged from insufficient to nonexistent, these are the factors that contribute to unsanitary living conditions. As these crippling living conditions were slowly addressed, the decline of
infectious diseases began.

The connection between living in abject filth and rampant disease is so obvious that it shouldn’t need to be explained, but it has been explained comprehensively. The scientific explanation is known as the filth theory of disease. Most doctors have never even heard of it. They are too busy being taught pharmaceutically influenced curriculum to learn the historical facts.

We used to be plagued with epidemics on a regular basis. When it comes to understanding how people lived, died, and what challenges they faced, the experts are not the physicians. The experts are the historians, the archeologists, and the anthropologists. Asking doctors what eradicated smallpox is like asking them detailed questions about black holes, inflation and deflation, or what events led to the American Revolutionary War. Most doctors are well read, and though they may be familiar with these topics, they are unlikely to be experts on them. These kinds of questions are best left to those who actually study these phenomena—the astronomers, economists, and historians respectively. To learn about history, consult the historians.

You Get More Mercury From Consuming Fish Than You Do From Getting Vaccines

Despite claims to the contrary, no one gets more mercury from consuming fish than from receiving a vaccine that contains thimerosal. There is a profound physiological difference between ingesting mercury and injecting mercury. When we are healthy, our digestive tract does a remarkable job of keeping toxic substances from entering our bloodstream. In either case, the mercury in seafood or vaccines is from an unnatural origin. Even though mercury naturally occurs in the
environment, the sheer amount of mercury that we are exposed to is problematic, and the majority of it is a direct consequence of vaccination and industrial pollution. No amount of mercury is good for us, for the environment, or for wildlife. The mercury in seafood is no doubt a serious health concern, but injecting mercury directly into our bloodstream is far worse than eating small amounts of it and is totally avoidable.

**Vaccine Manufacturers Do Not Make Much Money on Vaccines**

The pharmaceutical industry doesn’t produce anything out of a sense of altruism or for the greater good. For instance, even though we are in need of new antibiotics (many antibiotic resistant strains of bacteria have emerged as a real threat to our safety) all of the major pharmaceutical companies have publicly stated that they have no interest in developing new antibiotics. Their reasoning is simple: antibiotics are not profitable enough for them. It is far more profitable to develop drugs that are used over and over again, like vaccines, psychiatric medications, steroids, and statins. Disease and symptom management is far more profitable than developing drugs that actually cure or prevent illness. The first antibiotics were not developed by the industry but rather by independent scientists. Although antibiotics are no doubt egregiously overused, when used appropriately, they can save lives and cure infection. Big Pharma has the means to develop drugs that save lives and cure disease. In reality, this almost never happens because there is a lot more money to be made through symptom management. It is a comforting thought to believe that vaccines are made for the common good, but sadly they are made for money. The bottom line is the pharmaceutical industry only cares about the bottom line.

Each vaccine is worth billions of dollars, and *that* is why
there are hundreds of them in development. There is no liability on vaccines, and if a vaccine causes permanent injury (such as autism, ADHD, asthma, or immune disorders) most parents hold to the belief that medications are needed indefinitely to manage these syndromes. Obviously, this makes the pharmaceutical companies even more money.

Our children are sicker now than many generations past. As before, there are many reasons for this: diets heavy in processed foods, GMOs, sedentary lifestyles, and chemical pollutants. However, the primary reason that our young are in worse health than previous generations is vaccination. It is the profit motive that drives vaccine mandates. If vaccines were held to the same standards of liability as everything else that is bought and sold in America, vaccine research and production would halt faster than you could say “accountability”.

**Adverse Reactions to Vaccines are Rare**

If you don’t believe that vaccines are safe and effective, then industry hopes that you will believe that they are usually safe, and usually effective. Despite the fact that vaccines are filled with neurotoxins, Big Pharma has worked very hard to spread the belief that vaccine reactions are rare. This is, after all, what parents are told by their doctors. In truth, rare is the new normal.

At present, we are experiencing an epidemic of autism, ADHD, neurological disorders, asthma, SIDS, and several chronic illnesses. We are told by vaccine manufacturers that these rising rates of chronic illnesses are a mystery – that vaccines have nothing to do with it. If it is all coincidence, it is the biggest coincidence the world has ever seen.

Neurological disorders are on the rise and as more vaccines
are added to the CDC’s vaccine schedule the rates of autism rise along with increased vaccinations. Before vaccines were invented, SIDS was so rare as to have gone unnamed. In fact, SIDS happened so rarely that it almost didn’t exist. Unfortunately, this is the case with countless other syndromes. The same goes for autism. Before vaccines, no one, not even the experts, knew that such a neurological disorder even existed. Other chronic conditions such as autoimmune diseases and ADHD have also been on the rise, increasing alongside the ever-growing vaccine schedule.

A vaccine is designed to agitate the immune system into developing a lasting immune response. Sometimes this backfires in the worst and most noticeable way. What often goes unnoticed are problems that don’t tightly correspond with recent vaccines. A lasting immune response could leave us with what we see today, an epidemic of chronic illnesses. A genetic epidemic is a biological impossibility. However, environmental toxins injected into the body can account for this sudden rise in chronic illnesses. It is vaccines that are causing these rising rates of chronic illness, but proving it is very difficult when the truth is overshadowed by propaganda.

**Dr. Andrew Wakefield’s Research was Fraudulent**

Dubbed the “father of the anti-vaccine movement”, Wakefield has been both revered and vilified, depending on which side of the argument uses his name. Ironically, he is not anti-vaccine. But he dares to criticize them, and for that he’s been vilified. Wakefield has done expert research that fully supports his argument. The Japanese only administer the measles, mumps, and rubella vaccines separately, and yet no one claims all of the Japanese are fathers of anti-vaccine movements or frauds. The Japanese are also, on average, far healthier than most Westerners.
In 1998, Wakefield, Prof. John Walker Smith, Dr. Simon Burch, and 10 other co-authors published a paper in the Lancet, a British Medical Journal, which showed a possible correlation between the MMR vaccine and resultant gastrointestinal dysfunction along with developmental delays and autism. Though the paper itself did not state a conclusive causal effect, it did state the need for further study into the possibility that the MMR shot was responsible. In a radio interview, Wakefield went on to publicly bring attention to the possibility, criticizing the MMR shot and calling for separation of the three vaccines.

The publication, the publicity, and the controversy caused an uproar, which was credited with a sharp decline in vaccine compliance in the UK and to some extent in the U.S. The United Kingdom General Medical Council regulatory board (GMC) investigated and came to the conclusion, despite all evidence to the contrary, that the study and the published paper were fraudulent. The paper was retracted by the Lancet. Ten of the authors signed a letter retracting the claim that the MMR vaccine caused autism (even though the paper did not state that conclusion). Wakefield, Smith, and Burch did not sign the paper. They were brought up before the GMC on misconduct charges. Wakefield and Smith both lost their medical licenses.

In 2012, Prof. Smith won an appeal against the GMC. Although he was already retired, his license to practice medicine was restored. The reason why he was successful in getting vindicated while Wakefield was not is simple. Unlike Wakefield’s insurance, Smith’s insurance covered his expensive appeal. There was a clear ruling that the published paper and study met academic standards and that the GMC was at fault in their earlier ruling. The GMC has not taken the opportunity since then to restate Andrew Wakefield’s license or to clear his name. In order to fuel the vaccine propaganda machine, Wakefield’s work is to be unceasingly attacked, regardless of how scientifically valid it is. The same thing has been done
to Judy Mikovitz, and the movie Vaxxed. In the battle for the hearts and minds of the public, open scientific discourse is widely discouraged and crushed whenever possible.

**The Toxic Ingredients in Vaccines are Needed in Order to Make them Work**

Since the 1800s, homeoprophylaxis, a non-toxic, safe, and effective alternative to vaccination has been in use. Homeoprophylaxis or HP is the use of diluted and potentized disease products, called “nosodes” to elicit an immune response. Our bodies response to HP serves to educate our immune system in such a way as to make us highly resistant to the real pathogen. Homeoprophylaxis has been clinically shown to reduce the incidence of both infectious as well as chronic disease.

The goal of HP is the same as the stated goal of conventional vaccination – disease protection and improved health, but the differences are so profound as to make them a world apart. The most obvious difference is that the purity of nosodes as compared to the purity of conventional vaccines. HP nosodes contain no additives whatsoever – no antibiotics, no preservatives, no detergents, no foreign DNA, no unknown viruses, and no foreign DNA are present.

HP nosodes are administered on small sugar pellets. They dissolve on the tongue and enter the system by way of the natural route past mucous membrane. Here the natural process of disease recognition can begin in the way that Mother Nature intended. Bypassing this route by injecting a substance directly into the bloodstream is like an ambush attack to the immune system. There is no opportunity to mount a preliminary response in a biologically appropriate way. This proves that toxic ingredients are not needed to make a vaccine work.
High Vaccination Rates are Needed for “Herd Immunity”

Herd immunity does not have the narrow definition generally used today. Herd immunity as generated by vaccines has never been proven to exist, and there is no evidence that supports it. The kind of herd immunity that is evidence based is something else entirely. Real herd immunity is something that survivors of epidemics retain and pass on to their children. The survivors of plagues, both Europeans and those they encounter, all end up with some measure of herd immunity or they perish.

When the Desoto expedition first came through North America, infectious diseases came with them. Indigenous peoples of North America had no natural resistance to these diseases; they had no herd immunity. Long after the Desoto expedition was fought off, pathogenic microbes lingered, devastating the Native Americans. One disease after another spread through native cities, diseases like smallpox, cholera, typhoid fever, and so on. Europeans had centuries to develop resistance to these diseases. The Native Americans were not granted the same luxury of time. Over 90% of the North American continent’s original inhabitants were wiped out by these epidemics. Indigenous peoples of South America suffered these same ravages of disease. Thankfully, the survivors developed an increased resistance to these epidemics. The survivors had herd immunity, and this was passed on to their children. This is why their children showed resistance to European diseases and didn’t die from infectious disease 90% of the time like other natives.

No vaccines were developed that bolstered this immunity. It was and always has been an inherited resistance. Obviously, the children of those who survived diseases were more resistant to disease despite having not been previously exposed. The survival of the fittest, leaves us with herd
immunity, not vaccination.

**The Tetanus Vaccine Saves Lives, and is Needed Immediately Following an Injury**

The cure for tetanus, a painful and potentially fatal disease, has long been pursued by medical researchers. A cure for tetanus has proven elusive, so in the absence of a cure, the medical community has latched on to the idea of prevention. So far, these efforts have proven ineffective. It is blind faith that motivates the tetanus vaccine, faith in a vaccination that has never been proven to work. Harvard trained immunologist Tetyana Obukhanych, PhD explains:

*The tetanus toxin, called tetanospasmin, is produced by numerous C. tetani bacterial strains. C. tetani normally live in animal intestines, notably in horses, without causing tetanus to their intestinal carriers. These bacteria require anaerobic (no oxygen) conditions to be active, whereas in the presence of oxygen they turn into resilient but inactive spores, which do not produce the toxin. It has been recognized that inactive tetanus spores are ubiquitous in the soil. Tetanus can result from the exposure to C. tetani via poorly managed tetanus-prone wounds or cuts, but not from oral ingestion of tetanus spores. Quite to the contrary, oral exposure to C. tetani has been found to build resistance to tetanus without carrying the risk of disease.[2]*

Doctors typically give someone a DTaP vaccine as a treatment for tetanus infections. This is actually contraindicated. This is one of the most persistent falsehoods about vaccines, but one that can be quickly dispelled by simply reading the vaccine’s instructions. It reads:

“Tripedia vaccine is not to be used for treatment of B
pertussis, C diphtheriae, or C tetani infections.” [3]

It is used in this manner anyway, despite instructions to the contrary.

**You Need The DTaP Vaccine If You Are Pregnant**

Whooping cough or pertussis can kill people, especially infants, but so can the DTaP vaccine, and the vaccine often does. What is an expectant mother to do? We recommend taking the time to do the research and read the vaccine warning label. It reads:

*Animal reproduction studies have not been conducted with Tripedia vaccine. It is not known whether Tripedia vaccine can cause fetal harm when administered to a pregnant woman or can affect reproductive capacity. Tripedia vaccine is NOT indicated for women of child-bearing age.* [4]

Doctors recommend it anyway, even though it’s never been tested on pregnant women. The only thing that we know for sure about vaccines is that they tend to generate antibodies, but this does not equate to immunity or even resistance to infectious disease.

**Conclusion**

Vaccinations are an effort to eradicate infectious diseases, but sadly this effort has backfired. Diseases have become more prevalent in the young than in previous generations, and chronic illnesses are now commonplace. Measles, whooping cough, and other vaccine-preventable illnesses can and often do strike the well vaccinated.

Though governments claim it would be unethical to do a study
that compared vaccinated to unvaccinated children, the reality is they would not want the public to see just how much healthier unvaccinated children truly are. Despite the supposed ethical controversy, some independent scientists are studying this. Studies have begun to emerge that show that the unvaccinated are healthier than their vaccinated peers. A study from 1992 examined the health of children in New Zealand and found that, typically, unvaccinated children had fewer chronic illnesses than vaccinated children. A similar longitudinal study out of Germany showed the same results.

Truth will win out over propaganda eventually, but it will take some time. When the news boldly proclaims that vaccines do not cause autism, they are spreading propaganda, the kind of lies that are not supported by independent science. Ironically, when parents take the time to do the research or even read a vaccine warning insert, they are often labeled conspiracy theorists. According to Merriam-Webster, the definition of a conspiracy is “a secret plan made by two or more people to do something that is harmful or illegal”. Conspiracies can and do happen. They are aided and abetted by propaganda and by the willingness of those trusting enough to deceive themselves.
